

# All You Need is Cash: Corporate Cash Holdings and Investment after a Crisis

Andreas Joseph, Christiane Kneer and Neeltje van Horen<sup>\*</sup>

April, 2020

## Abstract

Cash is king as corporate revenues plummet during the Covid-19 lockdown. Evidence from the global financial crisis shows that firms with high pre-crisis cash holdings can invest during a crisis while their cash-poor rivals have to divest. This gives cash-rich firms a competitive advantage during the recovery period, resulting in a persistent and growing investment gap. The divergence in investment paths between cash-rich and cash-poor firms is particularly large for financially constrained firms and is absent during tranquil periods. Due to their ability to invest in a crisis, cash-rich firms can gain market share and accumulate more profits in the long-run. Cash balances at the onset of a downturn are therefore a key determinant as to whether firms emerge as winners or losers from a crisis.

**JEL Classification Codes:** E22, E32, E44, G32

**Keywords:** Firm investment, cash holdings, credit constraints, financial crisis

# 1 Introduction

The social distancing measures to contain Covid-19 have a sharp impact on corporate activity. With offices and factories shut and households under lockdown, many companies see their revenues slump. If firms cannot cover their ongoing costs, cash flow pressures could result in corporate insolvencies or force companies to lay off staff and scrap productive capital. This can lead to persistent scarring. Companies with large amounts of cash on their balance sheets are in a more comfortable spot. In this paper, we present evidence from the global financial crisis to show that cash balances at the onset of a downturn are a key determinant of whether firms emerge as winners or losers from a crisis in the longer run. Having cash at hand enables firms to continue to invest during a crisis when industry rivals have to divest. This gives initially cash-rich firms a competitive advantage when the economy recovers and allows them to outperform their cash-poor rivals long after the crisis has subsided.

We start by documenting three stylized facts based on UK firm-level data covering both SMEs and large firms. First, firms' cash holdings show large variation not only *across* but also *within* narrowly defined industrial sectors (Figure 1).<sup>1</sup> This means that at any given point in time some firms in an industry have large amounts of cash while others only very little.

Second, and possibly more surprising, for many firms, especially young and small ones, cash holdings tend to fluctuate substantially year-on-year (Figure 2).<sup>2</sup> This indicates that while for some firms their cash position in a given year is the result of a deliberate cash management strategy, for others it is the outcome of variations in production/sale patterns and resulting (volatile) profit and cash flow.

Third, the correlation between firms' cash holdings and their subsequent investment is very different in tranquil compared to crisis times. When we rank firms according to the size of their cash holdings relative to their industry rivals in the year 2000, only a weak relationship with investment over the period 2001-2007 emerges: both cash-rich and cash-poor firms increased their fixed assets over this period (Figure 3, top panel). When we rank firms based on their relative cash holdings just prior to the start of the global financial crisis instead, we see that a firm's cash position strongly correlates with its investment over the period 2007-2014 (Figure 3, bottom panel). While firms with cash continued to invest throughout the crisis,

---

<sup>1</sup>It is well-established in the literature that cash holdings differ importantly across industries. Cash holdings are for example more valuable in industries with volatile cash flows (Kim, Mauer, and Sherman, 1998; Opler, Pinkowitz, Stulz, and Williamson, 1999; Han and Qiu, 2007) and in industries where the correlation between cash flows and investment opportunities is low (Acharya, Almeida, and Campello, 2007).

<sup>2</sup>On average the 1-lag autocorrelation of a firm's cash holdings relative to its industry rivals is only 0.22 and even weaker for young and small firms. The distribution of the 1-lag autocorrelation of absolute cash holdings is very similar with the average autocorrelation equal to 0.20.

cash-poor firms were shrinking their fixed assets instead. And, perhaps more surprisingly, this divergence in investment behavior became even more pronounced during the recovery period. This suggests that having cash at hand when credit conditions tighten can give firms a considerable advantage, not only in the short-term but especially in the long-term.<sup>3</sup>

There are several reasons why a firm's cash holdings can impact its investment decisions more so during a crisis than during normal times. First, cash provides a firm with an internal source of funds when credit conditions tighten, external finance becomes more costly and cash flow declines.<sup>4</sup> A firm can use these internal funds to cover its expenditures, pay off debt, replace capital equipment and finance profitable investment projects (Froot, Scharfstein, and Stein, 1993).<sup>5</sup> Second, when asset prices decline cash preserves its value which protects the firm's net worth. This reduces a lender's exposure to losses and can prevent a (sharp) rise of the external finance premium (Bernanke and Gertler, 1989). Third, a cash-rich firm does not have to increase its cash holdings for precautionary motives in the wake of a negative economic or funding shock and can use these funds for investment instead (Almeida, Campello, and Weisbach, 2004; Berg, 2018).

For these reasons, firms with ample cash at hand can more easily continue to operate during a crisis. They will be able to replace fixed assets that have depreciated and can even seize profitable investment opportunities when they come along. Their cash-starved rivals by contrast will have to bypass or cancel profitable investment opportunities and will find it harder to replace depreciating fixed assets. They may even struggle to survive.<sup>6</sup> Thus, while the stock of fixed assets of cash-poor firms likely falls, cash-rich firms can maintain or even increase theirs, allowing an investment gap between cash-rich and cash-poor firms to open up.

These contrasting investment patterns bring about a shift in competition dynamics. Cash-rich firms are able to preserve their productive capacity and can even possibly expand it. At the same time the productive capacity of cash-poor firms shrinks. Cash-rich firms can further advance their competitive position if they can acquire assets at discounted prices

---

<sup>3</sup>The variation in cash holdings within industry is very similar in 2000 compared to 2006. As such the differential pattern cannot be explained by sharp differences in cash holdings in the two periods.

<sup>4</sup>During the global financial crisis the cost of external finance increased sharply as banks reduced the supply of credit (Ivashina and Scharfstein, 2010; Santos, 2011).

<sup>5</sup>Standard valuation models treat cash like the negative of debt which implies that cash does not have an independent impact and only net leverage (debt minus cash) should matter. The key underlying assumption of these models is that financing is frictionless: a firm that uses cash to pay off its debt today is expected to be able to issue new debt tomorrow under the same conditions. This assumption has been challenged even for publicly listed firms and during non-crisis times (Acharya, Almeida, and Campello, 2007) and is even less likely to hold during crisis episodes.

<sup>6</sup>While not focusing explicitly on the role of cash Campello, Graham, and Harvey (2010) show that firms that identify themselves as financially constrained during the crisis planned deeper cuts in employment and capital spending, were forgoing otherwise attractive investment opportunities and sold assets in order to fund operations.

from their struggling competitors or if their presence deters other firms from entering or investing (Benoit, 1984). In addition, they can exploit the weakness of their cash-poor rivals by strategically investing in R&D, the location of stores and plants, distribution networks or advertising (Campello, 2006) or by lowering their prices (Gilchrist, Schoenle, Sim, and Zakrajšek, 2017).

During the recovery phase when demand returns and credit conditions improve, cash-rich firms have more capacity to meet this demand. They can subsequently reinvest their earnings, increasing their productive capacity further. Cash-poor rivals, due to their loss in productive capacity, will have difficulties meeting demand making it harder to generating cash flow. As a result they will see their positions weaken further. This effect is reinforced if banks faced with weakened balance sheets and/or tighter regulation after the crisis are mainly willing to lend to low-risk firms. Furthermore, to the extent that corporate debt is collateralized by cash-flow (Lian and Ma, 2018) cash-rich firms will see their borrowing constraints lessen and cash-poor firms theirs tighten, making it even more difficult for the latter to catch up with the former.<sup>7</sup> As a consequence of these self-reinforcing dynamics, the investment gap between cash-rich and cash-poor firms that opened up during the crisis is amplified during the recovery period.

The feedback-loop described above implies that a firm’s pre-crisis cash position relative to its industry rivals is a strong predictor of a firm’s investment during the global financial crisis, but even more so during the recovery phase. In addition, it should predict a firm’s long-term market share and profit growth. We set out to test the validity of these predictions by studying the global financial crisis and its recovery period. We use a local projections framework (Jordà, 2005) and examine how a firm’s investment over different horizons between 2007 and 2014 responds to the financial crisis conditional on its pre-crisis cash holdings.<sup>8</sup> This allows us to test whether initial cash holdings affected investment during the financial crisis and assess whether the effect was amplified during the recovery phase when self-reinforcing dynamics set in.

We focus on a set of firms that survived both the global financial crisis and the recovery period. This way we ensure that changes in the cash-investment sensitivity over time cannot be attributed to firms that were exiting or entering the market. We control for a wide set of firms’ pre-crisis characteristics, including age, size, leverage, performance and investment, that might be correlated with a firm’s cash position and could also potentially affect its ability or

---

<sup>7</sup>Lian and Ma (2018) do not study UK firms, but focus on non-financial corporates in the US. They show that cash-flow based lending is more prevalent among larger firms and that the reliance on cash-flow based lending relative to asset-based lending is larger in the US compared to Japan.

<sup>8</sup>See Jordà, Schularick, and Taylor (2013), Favara and Imbs (2015), Mian, Sufi, and Verner (2017) and Wix (2017) for recent applications of local projections in finance.

willingness to invest during the crisis and recovery period. To control for demand shocks and investment opportunities we use 4-digit industry and regional fixed effects. The fixed effects absorb for each investment horizon the impact of industry (or regional) conditions, including industry-specific uncertainty, demand and other factors affecting all firms in an industry (or region) in the same way.

We use a firm-level dataset with balance sheet information of private firms and publicly listed companies based in the UK. It is manually constructed from Moody’s (previously Bureau van Dijk’s) FAME database and covers the period 1999 to 2014. This dataset is ideally suited for our purpose for several reasons. First, it covers small and young firms and is not confined to large, publicly listed companies. This is important for any analysis on the effects of (financial) crises as small and young firms are critical to a dynamic economy but they are more likely affected by a tightening of financial constraints as they typically require more lender screening and monitoring (Almeida, Campello, and Weisbach, 2004; Iyer, Peydró, da Rocha-Lopes, and Schoar, 2014). Second, it covers both the period leading up to the global financial crisis, the crisis itself and the recovery phase. This allows us to compare cash-investment sensitivities during the crisis and its aftermath with the sensitivities during the pre-crisis period. We can therefore test whether a tightening of credit conditions altered this sensitivity.

A potential concern with our identification strategy is that a firm’s cash policy might be endogenously related to its investment opportunities during and after a crisis. We address this concern in several ways. First, we measure the firm’s relative cash position in 2006, i.e. prior to the onset of the financial crisis. As the global financial crisis was unexpected, it is unlikely that firms were hoarding cash in 2006 in anticipation of a credit supply shock that would affect their future ability to invest. Second, we control for a wide range of firm characteristics that are correlated with a firm’s cash holdings and might also explain its (post-) crisis investment. Third, we test whether the results we document are a distinct feature of the crisis and the recovery period and do not reflect a common phenomenon. Fourth, we utilize cross-sectional differences as they relate to a tightening of financial constraints during the crisis at both the firm- and industry-level. Finally, we exploit the empirical regularity that for many firms in our sample cash holdings tend to fluctuate substantially year-on-year. This indicates that, at least for a subset of firms, cash does not represent some time-invariant unobserved firm characteristic, such as prudent management, which could be correlated with the firm’s ability to invest (or its need to divest) during the financial crisis. Instead for these firms, cash holdings in a given year are the result of year-on-year variation in sale and production patterns and resulting (volatile) cash flow. For this group of firms there is an element of luck involved as to how cash-rich or cash-poor the firm is when the credit cycle turns and therefore the firm’s

pre-crisis cash holdings are plausibly exogenous to its ability to invest during a crisis.<sup>9,10</sup>

Focusing on the crisis period itself, we find that firms with high initial levels of cash relative to their industry rivals invested relatively more. The differential effect is the result of two opposing forces: firms with cash maintaining or even growing their stock of fixed assets and firms without cash shrinking theirs. This result is robust to controlling for a wide set of firm characteristics including pre-crisis performance and investment and 4-digit industry fixed effects. We thus confirm the findings of Duchin, Ozbas, and Sensoy (2010) who document a positive, albeit short-lived, impact of cash on investment behavior of publicly listed firms in the US during the height of the global financial crisis. The findings are also consistent with those of Berg (2018) and Beck, Da-Rocha-Lopes, and Silva (2018) who show that firms with cash at hand reduce investment less in the short-term when faced with a credit supply shock.

But this is not where the benefit of having cash ended. As suggested by the mechanism described above, we find that the positive effect of cash not only persisted but became larger during the recovery phase. And the magnitude of the increase was very significant. When taking the average across all industries, our estimates indicate that a cash-rich firm (a firm in the 90<sup>th</sup> percentile of the relative cash distribution) kept its stock of fixed assets between 2007 and 2009 stable, i.e. this firm was able to replace all of its depreciating fixed assets during the crisis.<sup>11</sup> A cash-poor firm (a firm in the 10<sup>th</sup> percentile) decreased its stock of fixed assets by 4.7 percent instead; resulting in an investment gap of 4.7 percentage points. By 2014 the cash-rich firm had increased its stock of fixed assets by 5.0 percent, while the cash-poor firm had decreased its fixed assets by 6.3 percent. In other words, the size of the investment gap more than doubled during the recovery period to 11.3 percentage points.

Importantly, this cash effect was present for firms whose cash holdings were relatively stable and for firms whose cash holdings fluctuated significantly in the period leading up to the

---

<sup>9</sup>For the firms in our sample with volatile cash holdings, the correlation between year-on-year changes in cash holdings and 1-period ahead fixed asset growth varies widely and is on average close to zero (see Appendix Figure 1). This suggests that for most of our firms, year-on-year fluctuations in cash positions are not determined by their immediate investment plans (i.e. a firm reducing its cash buffer today in anticipation of a lack of investment opportunities tomorrow).

<sup>10</sup>Another concern can be the presence of unobserved credit lines. As shown by Ivashina and Scharfstein (2010) firms were drawing down their credit lines during the global financial crisis. This can positively affect their ability to invest during the crisis and the subsequent recovery period. However, as shown by Campello, Giambona, Graham, and Harvey (2011), during the crisis firms that had enough internal funds available choose not to use their credit lines. This suggests that credit lines are more expensive than having cash at hand especially for firms that become financially constrained. Indeed, Sufi (2009) finds that access to credit lines becomes more restricted following declines in borrower profitability. Acharya, Almeida, Ippolito, and Perez (2014) provide a theoretical rationale for this behavior by showing that credit lines can serve a liquidity monitoring role. This makes the cost of credit lines greater for firms with high liquidity risk. Furthermore, banks tend to increase interest rates and make loan provisions less borrower-friendly when firms, faced with a cash flow shock, draw on or increase their credit lines (Brown, Gustafson, and Ivanov, 2017).

<sup>11</sup>For this firm gross investment is positive as investment expenditure equals the depreciation of capital equipment, but net investment is zero.

crisis. In both cases we document a positive impact of having cash on investment during the crisis and a significant amplification effect during the recovery period. This reduces concerns that our results are driven by some unobserved firm characteristic. It suggests that having high or low levels of cash when the credit cycle turns, whether due to sheer (good or bad) luck or because of carefully managed cash buffers, has a strong impact on firms' long-term investment patterns after a crisis.

If it were generally the case that cash-rich firms invest more in the long-term than their cash-poor rivals, we should find a similar trajectory for the cash coefficient during a tranquil period. Instead, we find that during the period that preceded the crisis both cash-rich and cash-poor firms were growing their fixed assets with the difference being statistically significant only in the short-term and much smaller compared to what we observed during the crisis period. Importantly, we do not find an amplification of the cash-effect in the period preceding the financial crisis. This suggests that the tightening of credit conditions played a significant role in driving the effect we document.

Cross-sectional analyses utilizing firm and industry heterogeneity lends additional support to our hypothesis. We exploit the well-documented fact that young and small firms are more affected by credit supply shocks (Chodorow-Reich, 2014; Ongena, Peydro, and Van Horen, 2015; Cingano, Manaresi, and Sette, 2016). In line with this, we find that the impact of relative cash was particularly large for young and small firms, i.e. those firms that more likely became financially constrained during the crisis. In addition, cash-investment sensitivities were larger for firms operating in industries where the average firm is younger or smaller. In other words, and as expected, the benefits of having cash were especially pronounced in industries where firms more likely experienced a credit supply shock. Other industry characteristics such as capital intensity, competition or depth of crisis do not seem to play a role.

The underlying mechanism of the feedback loop we describe is the ability of cash-rich firms to maintain or even increase their productive capacity while cash-poor firms are forced to shirk theirs, giving cash-rich firms a competitive advantage. In line with this competition channel, we find that firms with high initial levels of cash captured market share from their cash-poor industry rivals during the crisis and this effect was amplified during the recovery phase. Again, we do not find that cash helped firms increase their market share during the pre-crisis period.<sup>12</sup> The positive impact of cash holdings on market share growth during the crisis and the recovery period was again largest for young and small firms and in industries

---

<sup>12</sup>Fresard (2010) finds for publicly listed companies in the US that firms with higher cash holdings do increase their market share in the short-run during tranquil times. However, besides focusing on a different set of firms, he studies market shares in terms of sales, while we (due to data limitations) study market shares in terms of assets.

where firms more likely became financially constrained. Besides increasing their market shares, cash-rich firms also accumulated more profits over the period 2007-2014 compared to their cash-poor rivals.

Our findings support the idea that companies with large cash reserves find themselves in a more comfortable spot when a crisis hits. Having cash at hand allows firms to gain a strategic advantage over their cash-poor rivals. The ability to continue to invest during a crisis gives cash-rich firms a competitive edge that does not only benefit them during the crisis but even more so in the subsequent recovery period. Our findings highlight the importance of having a liquid balance sheet when a crisis hits for a firm's long-term growth path in its aftermath. In addition, they show that focusing exclusively on the direct crisis episode severely underestimates the impact a crisis has on firm performance.

The remainder of the paper is structured as follows. The next section discusses how this paper contributes to the literature. Section 3 introduces the empirical strategy and the data. Section 4 reports the results on the long-run effects of cash on firm investment and Section 5 presents evidence on the impact of cash on market share growth and firm operating performance. Section 6 concludes.

## 2 Contribution to the literature

This paper lies at the intersection of the literature on the real effects of credit constraints and on corporate liquidity management. In the wake of the global financial crisis a large literature has emerged studying its consequences, focusing mainly on the short-term. Banks, faced with a deterioration of their balance sheets, increased the cost and reduced the supply of credit (Ivashina and Scharfstein, 2010; Santos, 2011). Firms dependent on credit from these banks responded to the tightening of credit conditions by cutting down on investment, employment and output (e.g. Campello, Graham, and Harvey, 2010). Young and small firms reacted especially strong (e.g. Chodorow-Reich, 2014; Ongena, Peydro, and Van Horen, 2015; Cingano, Manaresi, and Sette, 2016) as they were not able to compensate for the credit crunch by switching to other sources of external funding (Iyer, Peydró, da Rocha-Lopes, and Schoar, 2014). The health of banks' balance sheets critically determined the magnitude of their credit contraction (Puri, Rocholl, and Steffen, 2011), but firms' balance sheets played an important role as well. Firms that had to roll over a significant amount of debt during the crisis (e.g. Almeida, Campello, Laranjeira, and Weisbenner, 2012) or that faced bigger debt overhang (Kalemli-Ozcan, Laeven, and Moreno, 2018) were more affected by the crisis than others.<sup>13</sup>

---

<sup>13</sup>Focusing on the Great Depression, Benmelech, Frydman, and Papanikolaou (2019) show that financial frictions as a result of maturing corporate bonds had a strong negative causal effect on firm employment.

On the other hand, firms with ample cash on their balance sheet were less affected and continued to invest during the crisis (Duchin, Ozbas, and Sensoy, 2010).

While the short-term effects of the financial crisis are fairly well understood, we still know little about its long-run consequences. Two notable exceptions are Wix (2017) and Duval, Hong, and Timmer (2019). Both papers focus on the liability side of a firm's balance sheet and exploit heterogeneity in financial vulnerabilities as they arise from the amount of debt maturing during the crisis. Wix (2017) finds that (large) firms with a higher share of maturing debt reduced investment in the short-run, with no catch-up effect in the long-run. Duval, Hong, and Timmer (2019), focusing mainly on the long-term effects, find that six years after the crisis a significant TFP level gap still existed between firms with weaker and stronger pre-crisis balance sheets. We complement these works and focus on the asset side of a firm's balance sheet. We first confirm the findings of Duchin, Ozbas, and Sensoy (2010) that a liquid balance sheet insulated firms from the impact of the global financial crisis in the short-run. But this short-term effect is much smaller compared to the long-term effect, at least for the SMEs that dominate our sample. Having cash at hand puts a firm on an entirely different investment path that persists long after credit conditions have loosened again. Our findings thus not only show that cash is an important asset to have when the credit cycle turns, but also highlights that in order to assess the full impact of a financial crisis it is important to study the recovery period as well.

The importance of corporate liquidity management to lessen financial constraints has received ample attention in the literature. Already Keynes (1936) highlighted the advantage of a liquid balance sheet for undertaking valuable investment projects when they arise, particularly in the presence of financial constraints. In line with this, prior literature, focusing mainly on large, publicly listed corporates, shows that financially constrained firms hold more cash for precautionary motives (e.g. Opler, Pinkowitz, Stulz, and Williamson, 1999; Faulkender and Wang, 2006; Acharya, Almeida, and Campello, 2007) and that cash reserves allow financially constrained firms to invest more especially when their hedging needs are large (Denis and Sibilkov, 2010).<sup>14</sup> Firms tend to increase their cash holdings after a negative macroeconomic or funding shock (Almeida, Campello, and Weisbach, 2004; Song and Lee, 2012), which leads them to reduce investment (Berg, 2018) and employment (Bancchetta, Benhima, and Poilly, 2019). Others provide evidence of the protective effect of a liquid balance sheet on firm investment in the face of a contractionary monetary policy shock (Ottonello and Winberry,

---

<sup>14</sup>The findings in these papers are consistent with the idea that higher cash holdings are a value-increasing response to costly external finance. An alternative view presented in the literature is that financially constrained firms hold high cash reserves due to value-reducing agency problems and empire-building behavior of managers (Jensen and Meckling, 1976; Harford, 1999; Pinkowitz, Stulz, and Williamson, 2006; Dittmar and Mahrt-Smith, 2007; Harford, Mansi, and Maxwell, 2008).

2018; Jeenas, 2018) or a credit supply shock (Beck, Da-Rocha-Lopes, and Silva, 2018). We add to this literature by showing that cash not only protects firms from the immediate impact of a credit supply shock in the wake of a financial crisis, but that it enables them to gain a competitive edge over their credit constrained rivals that still benefits them several years after the initial shock. In line with Fresard (2010) we show that one mechanism behind the growing investment gap between cash-rich and cash-poor firms that we document is the ability of cash-rich firms to capture market share from their cash-poor rivals. Finally, we contribute to the literature by uncovering several empirical regularities as they relate to corporate cash holdings and investment decisions of SMEs which represent the vast majority of businesses. Due to data limitations, most of the literature has hitherto focused on publicly listed firms in the US but their cash and investment policies might be driven by very different considerations. We show that having a liquid balance sheet when the credit cycle turns is more important for young firms and SMEs, highlighting the importance of studying corporate cash policies of these types of firms as well.

### 3 Empirical methodology and data

Our paper aims to test whether a firm’s pre-crisis cash position relative to its industry rivals is a strong predictor of long-term investment after a financial crisis and whether changes in competition dynamics drive this. In this section, we explain the empirical methodology for our investment regressions and discuss the data and variables used for this analysis. The methodology and variables that we employ to analyze the competition mechanism are discussed in Section 5.

#### 3.1 Empirical methodology

We use a local projections framework (Jorda, 2005) to study how a firm’s cash position going into the crisis affects its investment decisions during and after the crisis.<sup>15</sup> Local projections allow us to estimate how a firm’s investment over horizon  $j > 0$  responds to the financial crisis conditional on the firm’s cash position relative to its rivals in 2006, i.e. two years before the crisis. As the global financial crisis was unexpected, it is unlikely that firms were hoarding cash prior to the crisis in anticipation of a credit supply shock that would affect their ability to invest once the crisis hit.

---

<sup>15</sup>Local projections have several advantages over computing impulse responses using vector autoregressions (VAR). They can be estimated by simple regression techniques, they are more robust to misspecification, analytical inference is simple and they can easily accommodate non-linearities and multiple fixed effects (Jorda, 2005).

We regress fixed asset growth of firm  $i$  between 2007 and horizon  $j$  on the firm's initial cash position and a number of control variables. We estimate the following regression model:

$$\Delta \ln FA_{i,07+j} = \beta_j \text{Relative cash}_{i,06} + \gamma_j X_i + \sum_{k=0}^1 \theta_{kj} \Delta \ln FA_{i,07-k} + \rho_{sj} + \vartheta_{rj} + \varepsilon_{ij}, \quad (1)$$

where subscript  $i$  indexes the firm and  $j$  the horizon over which fixed asset growth is measured. We set  $j$  to range from one to seven years to study firms' fixed asset growth up to 2014.  $\Delta \ln FA_{i,07+j}$  is defined as the log difference of fixed assets between 2007 and year  $2007 + j$ . As our focus is on fixed asset growth between two periods we implicitly control for all time-invariant firm characteristics. *Relative cash* captures the firm's cash holdings in 2006 as a share of its total assets and is measured relative to the cash holdings of the firm's rivals within narrowly defined 4-digit industries using  $z$ -scores;  $\gamma_j$  is a coefficient vector and  $X_i$  is a matrix of firm-level control variables that might affect a firm's investment decisions and may directly correlate with its cash position. In particular, we include two age dummies, *Mature* and *Old*, the dummy variable *Group* which indicates whether a firm is part of a corporate group or not, and the dummy variable *Public* which indicates whether the firm is publicly listed or not. We also include three continuous variables: *Size* which is defined as the log of total assets, *Leverage* which is defined as total liabilities over total assets and *Profits* which equals profits over total assets. All these control variables are measured in 2006. To control for the fact that investment decisions can be lumpy the model also includes pre-crisis annual fixed asset growth between 2005 and 2006 and between 2006 and 2007. In an extension of the model, we also include turnover growth over these years.  $\rho_{sj}$  is a vector of 4-digit industry fixed effects,  $\vartheta_{rj}$  is a vector of regional fixed effects, and  $\varepsilon_{ij}$  is the error term at horizon  $j$ . More detailed definitions of all variables are provided in the next section.

Regressions are estimated for each horizon separately using OLS and standard errors are clustered at the 4-digit industry level. As we estimate a separate regression for each horizon, including industry and region fixed effects is akin to including industry-year and region-year fixed effects in a panel regression. These fixed effects thus absorb all demand and productivity shocks at the industry and regional level that can affect a firm's investment decisions throughout the crisis and its aftermath.

The main coefficients of interest in regression (1) are the  $\beta_j$  coefficients. Our estimates for  $\beta_j$  measure the sensitivity of firms' investment decisions over horizon  $j$  to their cash holdings before the onset of the crisis. A positive estimate for  $\beta_j$  implies that fixed assets of firms with larger initial cash holdings relative to their rivals grow more over horizon  $j$ . Because of the dynamic nature of the coefficients, we will present the estimation results as graphs and plot the estimates of  $\beta_j$  over horizons  $j = 1, \dots, 7$ .

### 3.2 Firm balance sheet data

Our primary data source is the FAME database provided by Moody’s (previously by Bureau van Dijk). The FAME database is a subset of the more commonly used Amadeus (European firms) and Orbis (global firms) datasets that Moody’s provides. It includes balance sheet information, cash flow statements and profit and loss accounts of UK companies. The data are collated from the publicly available filings of each firm at Companies House, the official UK firm registrar, and therefore capture most of the UK’s corporate universe.<sup>16</sup> The dataset is different from datasets that are commonly used in the literature on the real effects of financial crises and corporate investment decisions such as Compustat or Worldscope. These datasets only contain information on large and publicly listed companies. The vast majority of companies in FAME by contrast are small and medium sized firms (SMEs) which are privately owned. The FAME dataset therefore allows us to study the post-crisis investment behavior of both SMEs and young firms, i.e. the kind of firms that are more likely to be affected by a tightening of financial conditions during the crisis.

A critical part of our identification strategy relies on comparing firms’ cash-investment sensitivities during the crisis and its aftermath with their sensitivities during the pre-crisis period. This comparison allows us to demonstrate that the usual relationship between cash holdings and long-term investment changed when credit constraints tightened during the crisis. To perform this comparison, we require a dataset that covers not only the global financial crisis and its recovery, but also the tranquil period before the crisis. The key complicating factor is that FAME is a live database and historical information of inactive or dissolved companies is only retained up to five years after firm exit. We would therefore introduce survival bias in the earlier years of our analysis if we relied exclusively on a recent FAME download of the firm data.

To obtain representative firm accounts for the pre-crisis period, we download archived vintages of firm accounting data and overlay the balance sheet information from these different vintages.<sup>17</sup> Each vintage contains ten years of financial accounts for active companies and five years for inactive or dissolved companies.<sup>18</sup> The accounts of a firm in each vintage are uniquely identified by the firm’s Companies House registration number and the account filing date. When overlaying different vintages of accounts, we retain non-missing balance sheet information from those firm’s accounts that were most recently filed. Thus, whenever balance

---

<sup>16</sup>Companies House collects and publishes data on registered companies subject to the Companies Act 2006, including limited liability firms and partnerships but excluding sole traders.

<sup>17</sup>As discussed in great detail by Kalemli-Ozcan, Sorensen, Villegas-Sanchez, Volosovych, and Yesiltas (2015) and implemented for the UK by Bahaj, Foulis, and Pinter (2019), the use of historical information and careful treatment of the data is crucial to construct an accurate firm-level panel using data provided by Moody’s.

<sup>18</sup>We use the following vintages: March 2007, April 2012 and May 2017.

sheet information for a firm and year is available from multiple vintages of data or sets of accounts, we prioritize the most recent vintage. This exercise significantly reduces survival bias and substantially improves data coverage.

All firms are by law required to report to Companies House, but reporting requirements vary by firm size. Basic information is available for all firms but many variables (such as EBITDA, turnover, employment, etc.) are only reported by a subset of large firms.<sup>19</sup> Furthermore, UK firms are not required to submit their accounts during a specific month of the year. Firms’ annual accounts therefore cover different 12-month periods depending on the reporting month. To determine which calendar year the firm’s accounts correspond to, we assign accounts reported in the first half of a year to the previous calendar year and reports submitted in the second half of a year to the current calendar year.<sup>20</sup>

Firms are classified by 4- digit codes of the 2007 UK Standard Industry Classification. We follow the literature and exclude firms that operate in industries that provide financial services or are dominated by the public sector.<sup>21</sup> We also exclude industries with less than 30 firms. We only use the unconsolidated accounts of firms to avoid double-counting and to ensure that we focus as much as possible on the domestic component of the activity of firms that operate internationally. Our dataset covers firms that are single entities and firms that are part of a group (10 percent of the firms in our sample). Firms that are part of a group can potentially also access capital from their parent which could reduce the importance of cash holdings as a determinant of a firm’s investment decisions. We control for this in our analysis.

### 3.3 Regression variables

Our dependent variable is the growth in fixed assets. Investment in fixed assets can be measured on a gross or net basis i.e. with or without depreciation. If investment expenditures equal the depreciation of capital equipment, then gross investment is positive, but net investment is zero. We focus on net investment as measured by the log difference in fixed assets since net investment matters most for the productive capacity of the firm.

Our key variable of interest is the level of corporate cash holdings prior to the global financial crisis, as measured by bank deposits over total assets. We are primarily interested in the amount of cash a firm holds relative to its rivals in the same industry. This is because the

---

<sup>19</sup>See Bahaj, Foulis, and Pinter (2019) for a detailed description of firm reporting requirements in the UK.

<sup>20</sup>The vast majority of accounts cover a 12-month period. Occasionally, we also observe irregular filings or multiple filings in a single year. In the case of irregular filings, we assign as the accounting year the year into which most of the accounting period fell. In case of multiple filings, we calculate weighted averages to match the usual 12-month reporting period.

<sup>21</sup>Specifically, we exclude firms operating in finance and insurance, public administration, education, human health and social work, activities of households as employers and activities of extraterritorial organizations and bodies.

competitive advantage that a firm potentially gains by holding cash buffers will depend on the cash holdings of its competitors. Furthermore, as is well established in the literature, the importance of cash holdings to mitigate financial constraints depends critically on industry characteristics. Cash holdings are for example more valuable in industries with volatile cash flows (Kim, Mauer, and Sherman, 1998; Opler, Pinkowitz, Stulz, and Williamson, 1999; Han and Qiu, 2007) and in industries where the correlation between cash flows and investment opportunities is low (Acharya, Almeida, and Campello, 2007).

To construct a measure of relative-to-rivals cash holdings, we follow MacKay and Phillips (2005) and Fresard (2010) and standardize the ratio of cash to total assets within each industry at the 4-digit level. Specifically, we compute *Relative cash* by subtracting from the firm’s cash holdings its industry mean and divide the difference by the industry standard deviation in 2006. Measuring cash this way accounts for the fact that a 5 percent cash deviation in an industry with a standard deviation of 3 percent provides more value than it does in an industry with a standard deviation of 10 percent.

We include a number of firm-specific variables to control for the main determinants of investment. Small firms and young firms tend to rely more on internal funds to finance their investment. It is therefore important to control for firm size and age to assess the independent effect of relative-to-rivals cash holdings. We define the variable *Size* as the log of total assets in 2006. We measure the age of each firm as the number of years between the firm’s incorporation date and 2006. Based on this variable we create two dummy variables to differentiate between firms at different stages of their life cycle: *Mature* which is one if the firm’s age in 2006 is between 10 and 19 years and *Old* which is one if the firm is 20 years or older (young firms are therefore in the omitted category).

A number of studies show that the level of debt had a negative effect on investment during the crisis period (see, among others, Duval, Hong, and Timmer, 2019; Kalemli-Ozcan, Laeven, and Moreno, 2018). As leverage might also be correlated with cash holdings, we control for *Leverage* measured as the firm’s total liabilities over total assets in 2006. Firms that have generated profits in the run up to the crisis also likely have higher cash holdings and might be better equipped to perform well during the crisis. To control for this we include *Profit* as measured by the firm’s profits over total assets in 2006.

Some of the firms in our sample are part of a group structure and have access to liquidity through their corporate group. Access to an internal capital market can mitigate financial constraints of affiliated firms (Boutin, Cestone, Fumagalli, Pica, and Serrano-Velarde, 2013). We include a dummy variable *Group* which is one if the firm has a parent and reports an ultimate owner in FAME. Firms that do not report an ultimate owner or whose ultimate

owning company name is the same as the firm name are considered as stand-alone entities.<sup>22</sup> Finally, we include the dummy variable *Public* to account for the fact that publicly listed firms have access to additional sources of external finance.

Investment tends to be lumpy and is often partially financed with internal funds. Firms with low cash holdings in 2006 might have invested in the preceding years and might have lower investment needs in the years to come. To control for this we include a variable that captures annual investment of the firm in the pre-crisis period, *Pre-Investment*, and that equals the log difference of fixed assets between 2005 and 2006 and between 2006 and 2007.

For the subset of firms for which we have more detailed balance sheet information we include an additional control variable capturing the firm’s pre-crisis performance which could be correlated with both cash holdings and future investment opportunities. We control for *Pre-Turnover* which is defined as the log difference in turnover measured over the same period as *Pre-Investment*. To limit the effect of outliers, we drop observations below the first and above the 99th percentile for the continuous firm variables.

Our analysis focuses on the set of firms that survived both the crisis and the recovery period. This to ensure that change in the cash-investment sensitivity over time cannot be attributed to firms that are exiting or entering the market. In addition, we only include firms with complete data on relative-to-rivals cash, the control variables and investment over all horizons. The sample for our baseline investment analysis thus consists of 235,396 firms and the sample for our extended analysis which also controls for pre-crisis turnover consists of 34,519 firms. Descriptive statistics for these firms are shown in Table 1.

### 3.4 Characteristics of cash-rich and cash-poor firms

Figure 1 shows that cash holdings vary substantially *across* industries. Industry averages of cash holdings range from seven to around 50 percent of total assets, with a mean across all industries of 20 percent. This wide variation in average cash holdings reflects the fact that hedging needs and the volatility of cash flows differ across industries. Importantly, cash holdings also vary substantially *within* industries. On average, the standard deviation of firms’ cash holdings as a share of total assets is 20 percent. This is the variation we will exploit throughout the paper.

Table 2 sheds light on the characteristics of firms with high or low cash holdings relative to industry rivals. Cash-rich firms are defined as those in the upper quartile of the relative-to-rivals cash distribution in 2006 and cash-poor firms are those in the lower quartile. Cash-rich firms hold on average 57 percent of their balance sheet in liquid form, while cash-poor firms

---

<sup>22</sup>We thank Bahaj, Foulis, and Pinter (2019) for sharing this information with us.

only hold 3 percent of total assets in cash. Comparing other pre-crisis characteristics of the two types of firms, we find that cash-rich firms tend to be small, somewhat younger, have less fixed assets, are less leveraged and are more profitable. We do not observe a difference in pre-crisis investment between cash-rich and cash-poor firms.

## 4 Long run effects of relative-to-rivals cash on investment

In this section, we examine whether a firm’s pre-crisis cash position relative to its industry rivals affects its investment during the financial crisis and whether the impact is amplified during the recovery period.

### 4.1 Results: Post-crisis investment and relative-to-rivals cash

Figure 4 graphically presents the results from the local projection regressions as specified in equation (1). The solid lines depict the  $\beta_j$  estimates for each horizon. The two dotted lines indicate the 90 percent confidence intervals. The panel on the left shows the estimates for the full sample of firms. The positive and significant coefficient estimates for the first two horizons indicate that firms with high cash holdings going into the crisis experienced higher growth in their fixed assets relative to their cash-poor rivals during the crisis. We thus confirm the findings of Duchin, Ozbas, and Sensoy (2010) who document a positive impact of cash on investment behavior of publicly listed firms in the US during the height of the global financial crisis. The findings are also consistent with those of Berg (2018) and Beck, Da-Rocha-Lopes, and Silva (2018) who show that firms with cash at hand reduce investment less in the short-term when faced with a credit supply shock.

Importantly, the coefficient continues to be positive beyond the initial crisis years and even increases over the recovery period. In other words, the positive impact of high relative-to-rivals cash is not only persistent but is amplified over time. This suggests that firms with relatively high levels of cash prior to the crisis continued to invest more compared to their low-cash rivals even when the crisis subsided, credit became more readily available and demand returned. Figure 5 graphically illustrates the economic magnitude of these results. The figure shows the implied difference in cumulative fixed asset growth between cash-rich and cash-poor firms during the crisis (2007-2009) and during the crisis *and* recovery period (2007-2014). Cash-rich firms are those firms at the 90<sup>th</sup> percentile of the relative cash distribution and cash-poor firms are those at the 10<sup>th</sup> percentile. Taking the average across all industries, we estimate that the cash-rich firm kept its stock of fixed assets between 2007 and 2009 stable. In other words, this firm was able to replace all of its depreciating fixed assets during the

crisis, i.e. its gross investment was positive, but its net investment zero. The cash-poor firm decreased its stock of fixed assets by 4.7 percent instead; a difference of 4.7 percentage points. By 2014 the cash-rich firm had increased its stock of fixed assets by 5.0 percent, while the cash-poor firm had decreased its fixed assets by 6.3 percent. In other words, the difference in investment almost tripled during the recovery period to 11.3 percentage points. This shows that focusing exclusively on the direct crisis episode importantly underestimates the impact of a financial crisis on firm investment.

While our model controls for investment opportunities at the industry level by including granular industry fixed effects, it does not control for investment opportunities at the firm level. This could bias our results if cash holdings are correlated with the firms' investment opportunities in the years ahead. Firms might decide to hold more cash precisely because they expect their investment opportunities to be greater in the long run. This is usually addressed by including Tobin's  $q$  as a control variable. Since Tobin's  $q$  is only available for publicly listed firms, we instead extend the model by controlling for the pre-crisis performance of the firm as captured by its turnover growth in the two years prior to the crisis. Firms that perform well may have higher earnings that they can hold as cash. At the same time, high-performing firms might have better investment opportunities in the future. If this is the case, then the positive relationship between cash and long-term investment might not be driven by a tightening of credit conditions but by firm performance. As only larger firms report turnover in the UK, we estimate this extended model for a much smaller sample of large firms. The coefficients in Figure 4 (right hand panel) show a pattern similar to the baseline regressions including the strong amplification effect over longer horizons.<sup>23</sup>

As argued in the introduction, the persistence of relative cash is rather low for most firms (on average the autocorrelation over the period 2000-2006 is only 0.22). But there exists a lot of heterogeneity across firms with some firms being persistently cash-rich or cash-poor while others see their relative cash holdings fluctuate substantially over time. This indicates that for some firms their cash position in 2006 is the result of a long-term strategy to maintain a liquid or illiquid balance sheet. For other firms, it is more the outcome of year-on-year variation in production and sale patterns and resulting (volatile) profit and cash flow. This reduces concerns that *Relative cash* proxies for some time-invariant firm characteristic such as prudent management which could be correlated with a firm's ability to invest during a financial crisis. At least for the subset of firms with fluctuating cash holdings there is an element of luck involved as to how cash-rich or cash-poor the firm is when the credit cycle turns and therefore

---

<sup>23</sup>We also experimented with adding turnover volatility (measured as the standard deviation of turnover relative to total assets between 2000 and 2006) as a proxy for risk as another control variable. The results are materially the same, but the sample halves and turnover volatility is insignificant so we decided not to include it. Results are available upon request.

the firms' cash holdings in 2006 are plausibly exogenous to the firm's ability to perform well during a financial crisis. Exploiting these to some extent random fluctuations in production and sales patterns is similar in spirit to exploiting heterogeneity in the share of debt that was scheduled to mature during the crisis as pioneered by Almeida, Campello, Laranjeira, and Weisbenner (2012).

To examine whether the cash-effect we document maintains for firm with stable and with more volatile cash holdings, we split our sample into firms with weak, intermediate and strong autocorrelation (Figure 6). When we compare the estimates of the cash-investment sensitivity we find that the cash coefficient is positive and significant for all three groups and in all three cases the effect is amplified over time.<sup>24</sup> In other words, having high levels of cash when the credit cycle turns, whether due to sheer luck or because of carefully managed cash buffers, positively affects firms' long-term investment patterns after the crisis.

## 4.2 Results: Investment during the pre-crisis period and relative-to-rivals cash

Next, we examine whether the amplification effect is a distinct feature of the financial crisis and its aftermath (henceforth called "crisis sample" or "crisis period" ). To this end we estimate a similar model for the pre-crisis period. If it were generally the case that cash-rich firms invest more in the long-term than their cash-poor rivals, we should find a similar trajectory of the cash-investment sensitivity parameter for this period.

We measure a firm's cash position in 2000 and trace out the cash-investment sensitivity parameter for the period 2001-2007.<sup>25</sup> We choose a horizon of six rather than seven years to ensure that our pre-crisis analysis does not overlap with the crisis period. The control variables are the same as in the baseline crisis model and are measured in 2000, except for *Pre-Investment* which is defined as annual fixed asset growth between 1999 and 2000 and between 2000 and 2001. As before, we focus only on the set of firms which are active over the full pre-crisis period and that have complete data on relative-to-rivals cash, the control variables and investment for all horizons. This leaves us with a sample of 158,175 firms.

The results shown in Figure 7 are striking. Contrary to our estimates for the 2007-2014 period, the  $\beta_j$ -coefficients for the pre-crisis period are only significant for the first two years

---

<sup>24</sup>As we are only able to compute the autocorrelation for the subset of firms which have information on their cash-holdings for each year between 2000 and 2006, these regressions are based on a smaller subset of 115,494 firms. As this sample is biased towards older firms for which (as we will show in the next section) the cash-investment sensitivity is weaker, the coefficients for the different subsets of firms are lower compared to the coefficients for the full sample of firms as used in Figure 4.

<sup>25</sup>The distribution of cash holdings at the 4-digit industry level is very similar in 2000 and in 2006, with an industry mean of 17 percent and a standard deviation of 19 percent.

(at the 10 percent level) and become insignificant thereafter. Not only are the coefficients for the pre-crisis sample much smaller than (and statistically different from) the coefficients for the crisis sample, the amplification effect that we document for the crisis period is absent during the pre-crisis period.

Figure 8 graphically illustrates the difference in long-term investment behavior between cash-rich and cash-poor firms comparing the pre-crisis and crisis periods. Based on the estimated  $\beta$ -coefficient for the 6<sup>th</sup> horizon (the last horizon of our pre-crisis period), we find that in the pre-crisis period a cash-rich firm increased its stock of fixed assets by 4.9 percent and a cash-poor firm by 3.8 percent and the difference between the two was 1.2 percentage points (and statistically insignificant).<sup>26</sup> By contrast, in the crisis period a cash-rich firm grew its stock of fixed assets by 3.4 percent, while a cash-poor firm shrank its stock by 7.9 percent, a difference of 11 percentage points. These numbers demonstrate that the difference between the two periods is mainly driven by the behavior of cash-poor firms. While initial cash-poor firms increase their fixed assets over the long-run in normal times, they shirk their fixed assets in crisis times instead.

A potential concern with this analysis is that firms in the crisis sample could be different from those in the pre-crisis sample. If the sample of firms we observe in the pre-crisis period contains a larger share of firms with a naturally low cash to long-term investment sensitivity this might explain the difference between the two periods. To ensure that this is not driving our results and that firms in the two samples are comparable we match a firm from our crisis sample with a firm from the pre-crisis sample along a number of key characteristics and re-estimate the model for the two periods based on this smaller set of matched firms. We require the two firms to match exactly in terms of their 4-digit industry, region, age and size group and the quartiles of leverage, profits and investment, where for the crisis sample all variables are measured in 2006 and for the pre-crisis sample in 2000. This leaves us with a matched sample of 72,366 firms for each period. The estimates for  $\beta_j$  using the matched samples are shown in the right-hand side panel of Figure 7. The results are very similar to those for the unmatched samples, except that for the pre-crisis sample now only the coefficient for the second horizon is statistically significant.

Given that our database starts in 1999, we choose 2001 as the beginning of our pre-crisis period to maximize the horizon over which we can estimate  $\beta_j$  before the start of the financial crisis. This coincides with the aftermath of the dot-com crash in 2000 which could affect our results even though the effect on the UK economy was relatively weak compared to the US. To ensure that our findings using 2001 as the starting year are representative of

---

<sup>26</sup>A cash-rich firm is a firm at the 90<sup>th</sup> percentile of the relative-to-rivals cash distribution and a cash-poor firm is at the 10<sup>th</sup> percentile.

pre-crisis trends more generally, we test whether results change when we begin our analysis for the pre-crisis period in 2002 or 2003 instead. Reassuringly, when we use 2002 or 2003 as starting years (and accordingly measure relative cash in 2001 or 2002) we find that the results are similar to those obtained for our pre-crisis sample starting in 2001 (Appendix Figure 2).

An additional concern could be that the industries in our sample underwent some structural changes between 2001 and 2007. If industries went through substantial consolidations, this could imply that an observational similar firm has a different position in its industry in 2001 compared to 2007 which might affect its relative investment opportunities and the way they are driven by the firm’s cash holdings. However, when we compare concentration measures for our 4-digit industries using firm-level turnover data from the Office for National Statistics in 2001 and 2007 we do not find any material changes in concentration. This implies that it is unlikely that the differences we document between the pre-crisis and crisis period are driven by underlying changes in the industries. Furthermore, the finding that our pre-crisis results are very similar when we take 2003 as our starting year is also reassuring as one would expect structural changes to take longer than 4 years to have a material impact.

Summarizing, the results show that the impact of cash on investment was very different in the pre-crisis period compared to the crisis period and its recovery. This suggests that the tightening of credit conditions played an important role in driving the effect we document.

### **4.3 Results: Cross-sectional analysis**

To provide additional support to the hypothesis that a tightening of credit conditions makes cash more valuable for firms, we next perform a number of cross-sectional analyses exploiting firm and industry heterogeneity as they relate to a tightening of financial constraints during the crisis.

#### **4.3.1 Firm-level**

First, we conduct a cross-sectional analysis based on firm-level measures of access to external finance. If liquid assets were beneficial because credit conditions deteriorated during the crisis, this effect should be particularly strong for firms that were more affected by a reduction of banks’ credit supply. We do not observe the bank-firm lending relationship, so we cannot differentiate between firms that had a lending relationship with banks more or less affected by the global financial crisis (e.g. Chodorow-Reich, 2014). Instead, we use two proxies for financial constraints at the firm-level that are commonly used in the literature to test whether cash-investment sensitivities varied with firms’ exposure to credit supply shocks: the age and size of the firm. Small and young firms typically require more lender screening and monitoring

and are therefore more likely to be affected by a tightening of financial constraints (Almeida, Campello, and Weisbach, 2004; Iyer, Peydró, da Rocha-Lopes, and Schoar, 2014).

First, we split our crisis sample into young firms (less than 10 years old in 2006) and old firms (20 years or older in 2006) and estimate the regression for the longest horizon, i.e. we use fixed asset growth between 2007 and 2014 as the dependent variable. The results are presented in the upper panel of Table 3. For brevity, we only display the cash coefficients. The p-value associated with the F-test that compares the coefficients between the two groups is derived from the pooled regression in which we interact all variables with a dummy that is one if the firm is old. The results show that when comparing young and old firms, the coefficient is significantly larger for young firms. Quantitatively, a young and cash-rich firm had increased its stock of fixed assets by 14.6 percentage points more than a young and cash-poor firm by 2014. For old firms this difference was only 7.2 percentage points.

Next we examine the difference between small and large firms, where small firms are those in the lowest quartile of the size distribution and large firms those in the highest quartile of the size distribution. The results (Table 3, lower panel) show that, as expected, the cash-investment sensitivity over the horizon 2007-2014 is also larger for small firms, but the difference between large and small firms is just statistically insignificant (p-value 0.14). Quantitatively, a small and cash-rich firm grew its stock of fixed assets by 18.7 percentage points more than a small and cash-poor firm by 2014. For large firms this difference was only 12.9 percentage points.

These findings are consistent with the idea that a tightening of credit conditions made cash more valuable and enabled firms with cash to continue to invest while their cash-poor rivals needed to divest.

### 4.3.2 Industry-level

To further uncover the drivers behind our findings, we now exploit the diversity in industries that is present in our dataset. This not only helps us to put aside any possible remaining endogeneity concerns, but also furthers our understanding of the circumstances under which cash is particularly valuable for firms when a financial crisis hits.

First, to strengthen the causal interpretation of our findings we identify sectors in which firms likely became more financially constrained during the crisis. If cash holdings provide a firm with a strategic advantage, the impact of relative-to-rivals cash should be larger in industries where the firm's rivals face more difficulties obtaining external funds during the crisis. As argued previously, firms that are small and young are more likely to become financially constrained during a crisis. We therefore expect a firm's cash holdings to have a bigger impact on its long-term investment if it operates in an industry where other firms (i.e.

the firm’s rivals) tend to be small or young.

To test this prediction, we follow Fresard (2010) and measure financial constraints affecting the firm’s rivals as the mean size and the mean age of firms within the 4-digit industry in 2006.<sup>27</sup> We then rank the industries based on each of the two variables and assign firms in the bottom and top industry quartiles to the “low” and “high” category, respectively. For each industry characteristic we then estimate equation (1) separately for the “low” and the “high” subsamples and compare the cash-investment sensitivities for the longest horizon, i.e fixed asset growth between 2007 and 2014.

The results in Panel A of Table 4 are fully in line with our predictions. For both industry characteristics, we find that the long-term effect of cash is larger when the firm’s rivals are more likely to face tighter financial constraints. The cash coefficient is positive and significant at the one percent level in industries where the mean firm is small or young. The cash coefficient is also significant in industries where rivals are older and larger, but the cash effect is much smaller. Cash coefficients for firms operating in the top and bottom quartile industries are significantly different from each other at the one percent level, irrespective of our measure of financial constraints.

Beyond the financial constraints that rivals’ face, other industry characteristics might also affect how beneficial cash is for a firm’s investment during the crisis and recovery period. We investigate these in panel B of Table 4. First, we examine whether it matters whether the industry is more labor or more capital intensive. We capture this by taking the mean fixed asset to total asset ratio of firms within the 4-digit industry in 2006 and again compare industries in the top and bottom quartile of the industry distribution. The results indicate that the cash-investment sensitivity is similar for industries that are labor intensive and those that are capital intensive.

The fierceness of competition a firm faces in an industry could determine how beneficial cash is. Using firm-level turnover data from the Office for National Statistics (2017), we calculate the Herfindahl-Hirschman Index (HHI) for each industry at the 4-digit level in 2006. The HHI can range from 0 to 1, where a higher index indicates that an industry is more concentrated. We do not take a stance on how high or low the HHI should be for an industry to be concentrated or competitive but compare firms in the bottom quartile to those in the top quartile of the industry HHI distribution instead. We find that cash has a positive impact on firm investment in industries with both high and low concentration. The coefficient is larger for firms operating in concentrated markets, but the difference is not statistically significant.<sup>28</sup> In both concentrated and competitive industries, cash holdings present an important competitive

---

<sup>27</sup>Results are very similar if we use the median age and size.

<sup>28</sup>Results are very similar when we use a measure of HHI based on employees.

advantage during a crisis and its recovery phase.<sup>29</sup>

Finally, we examine if the extent to which an industry suffered from the crisis affected the cash-investment sensitivity. A priori it is not obvious under which conditions cash would be more valuable. On the one hand, more opportunities to purchase fixed assets at discounted prices from failing or shrinking rivals could arise in industries that were hit hard by the crisis. Furthermore, lenders more likely withdraw funding from these sectors, making cash even more valuable. On the other hand, investment opportunities of cash-rich firms in declining industries with weak demand might be limited and very risky reducing the strategic advantage of holding cash.

To test which effect dominates, we measure the depth of the crisis at the 4-digit industry level based on the growth in value added between 2007 and 2010. The data are again from the ONS. Comparing firms in industries in the bottom quartile of the industry growth distribution with those in the top quartile, we find that cash holdings allowed firms to invest more in industries that weathered the crisis relatively well as well as in industries which suffered a severe downturn during the crisis.

Overall, these results support the view that cash holdings provided firms with a strategic advantage over their cash-poor rivals which persisted during the recovery period. Cash benefited especially those firms that were active in industries where rivals' access to external finance deteriorated, while other industry characteristics played less of a defining role.

## 4.4 Results: Tangible vs intangible fixed assets

Up till now we focused on investment in total fixed assets, without differentiating between its subcomponents. Fixed assets consist of on the one hand tangible fixed assets such as property, plant and equipment and on the other hand intangible fixed assets such as copyrights, trademarks, patents, licenses and brand value. In this section we disentangle these two subcomponents in order to shed light on which type of investment is driving our findings.

Only a small subset of large firms (16,616) report tangible and intangible fixed assets. For these firms we trace out the cash-investment sensitivity coefficient separately for total, tangible and intangible fixed asset growth. The results are provided in Figure 9. The estimates clearly show that relative cash only affects investment in tangible fixed assets. Cash does not seem to impact investment in intangible fixed assets.

A number of factors can explain this difference. First, as is evident from Figure 5 the cash effect is the result of two opposing forces: the ability of cash-rich firms to continue to

---

<sup>29</sup>Note that even in concentrated markets, often significant competition exists between small firms that compete locally. A case in point is the grocery store industry which is dominated by a few large supermarket chains, but in which many small corner stores compete with each other.

invest and the need of cash-poor firms to divest. It is easier for a cash-starved firm to reduce its stock of tangible fixed assets, for example by not renewing its car park, compared to reducing its intangible fixed assets. In addition, the weaker results on intangible assets could also be related to the greater difficulty of measuring them. As they are non-physical assets they are harder to value and simple depreciation rates cannot be applied. Third, accounting standards mandate that a business cannot recognize any internally-generated intangible assets (with some exceptions), only acquired intangible assets. This means that intangible assets listed on a balance sheet were most likely gained through the acquisition of another business, or were purchased outright as individual assets. Because of this any investment in internally-generated intangible assets will not be captured by the data.

## **5 Relative-to-rivals cash, market share growth and operating performance**

In the previous section, we documented the emergence of an investment gap between cash-rich and cash-poor firms during the crisis which was amplified during the recovery period. In this section, we explore whether competition dynamics were a possible driver behind the widening investment gap and examine how cash affects firms' market share growth and operating performance.

### **5.1 Competition dynamics**

When credit conditions tighten, firms that are starved of cash find it difficult to replace depreciating fixed assets, might be forced to liquidate fixed assets and need to forgo profitable investment opportunities. Their cash-rich rivals by contrast can draw on internal resources to continue to operate, to replace depreciating fixed assets and to even seize profitable investment opportunities. As the capacity of cash-poor firms to meet demand declines, cash-rich firms can capture market share from these shrinking or failing firms. Thus, even if demand contracts during a crisis, the market for cash-rich firms may actually expand.

Cash-rich firms can improve their positions further if they are able to acquire assets at discounted prices from their struggling competitors. In addition, they can invest in competitive strategies that allow them to further increase their market share at the expense of cash-poor rivals, such as investing strategically in R&D, the location of stores and plants, distribution networks or advertising (Campello, 2006). Furthermore, the presence of firms with large amounts of cash can deter rivals from entering a market or from expanding their capacity (Benoit, 1984). Cash reserves may also allow firms to strategically lower their prices to steal

market share from financially weak competitors that have to maintain or increase their prices in order to generate cash flow (Gilchrist, Schoenle, Sim, and Zakrajšek, 2017).

When the crisis subsides and the recovery sets in firms that were able to invest and capture market share during a crisis are in a better position to meet the demand. This improves their earnings and strengthens their balance sheets, allowing them to capture even more market share and to keep investing. Firms that are cash-poor at the onset of a crisis will find it hard to catch up with their cash-rich rivals and continue to see their positions weaken even when credit conditions improve. In other words, feedback effects ensure that the shift in competition dynamics during the crisis are amplified during the recovery phase.

This section assesses whether there is evidence in favor of the mechanism outlined above. We test how pre-crisis cash holdings affected a firm’s market share growth during the financial crisis and the recovery phase. This will allow us to assess whether the amplification of the investment gap over time could have been driven by the ability of cash-rich firms to gain market share which subsequently put them on a higher growth trajectory relative to their cash-poor rivals.

## 5.2 Regression specification

Similar to our investment regressions, we test how a firm’s market share growth over the horizon  $j > 0$  was affected by the financial crisis conditional on the firm’s cash position relative to its rivals just before the crisis. We regress firm  $i$ ’s market share growth between 2007 and year  $2007+j$ ,  $\% \Delta MShare_{i,07+j}$ , on the firm’s cash position and a number of control variables. Market share is defined as the ratio of the firm’s assets over the total assets in its 4-digit industry.<sup>30</sup> Market share growth therefore measures a firm’s asset growth relative to its competitors. We estimate the following regression model:

$$\% \Delta MShare_{i,07+j} = \beta_j Relative\ cash_{i,06} + \gamma_j X_i + \sum_{k=0}^1 \theta_{kj} \% \Delta MShare_{i,07-k} + \vartheta_{rj} + \varepsilon_{ij} \quad (2)$$

where subscript  $i$  indexes the firm and  $j$  the horizon over which market share growth is measured, with  $j$  ranging from one to seven years. *Relative cash* is defined as the cash holdings of the firm relative to the cash holdings of its rivals as measured in 2006. The control variables are the same as in specification (1) and include the firm’s size, age, leverage, performance and

---

<sup>30</sup>Ideally, a firm’s market share is measured in terms of its sales. However, in the UK this variable is only available for a subset of large and old firms. Since particularly small and young firms benefit from having large cash holdings as the results in Section 4.3.1 indicate, limiting the sample to large and old firms for which this variable is available would lead to a downward bias. We therefore decided to measure a firm’s market share in terms of its total assets.

whether it is part of a group or publicly listed. In addition, we control for pre-crisis market share growth (one and two periods lagged) in order to capture firm characteristics that may have driven the firm’s competitive position in the past.  $\vartheta_{rj}$  is a vector of regional fixed effects and  $\varepsilon_{ij}$  is the error term at horizon  $j$ . As the dependent variable is a relative-to-industry variable all industry-specific factors are already removed from the estimates and there is no need to include industry fixed effects. Regressions are again estimated for each horizon separately using OLS and standard errors are clustered at the 4-digit industry level. As before, we focus on the set of firms that survived the crisis and recovery period and for which complete data on relative-to-rivals cash, the control variables and market share growth are available for all horizons. This leaves us with a sample of 225,613 firms.

We also examine to what extent the relationship between cash and market share growth differs during the pre-crisis period. Fresard (2010), studying publicly listed US firms, shows that in normal times cash-rich firms systematically increase their market share (in terms of sales) in the short-run at the expense of their cash-poor rivals. He finds that this effect is larger when a firm’s rivals face tighter financing constraints, suggesting that the short-term relationship between cash and competition that he documents might be stronger during a crisis in line with our predictions. We estimate a similar model for the pre-crisis period where relative-to-rivals cash is now measured in 2000 and model (2) is estimated for each horizon between 2001 and 2001 +  $j$ , with  $j$  ranging from one to six. Our pre-crisis sample contains 158,175 firms. We estimate the models for the crisis and pre-crisis period again both for the full sample and for a matched sample of 72,366 firms

### 5.3 Results: Market share growth and relative-to-rivals cash

Figure 10 presents the  $\beta_j$  estimates for each horizon. The panel on the left shows the estimates for both the crisis and the pre-crisis period for the full sample of firms and the panel on the right shows the coefficients for the matched sample. The results indicate that firms with high levels of cash relative to their rivals prior to the crisis experienced higher market share growth during the crisis and the subsequent recovery period. In line with the mechanism outlined above, the coefficient follows an upwards trajectory in both the full and the matched samples. By contrast, we do not find a significant effect of relative-to-rivals cash on market share growth in the pre-crisis period.<sup>31</sup> Taking the estimates from the full sample, 7 years after the financial crisis a cash-rich firm had increased its market share by 3.7 percentage points more than a

---

<sup>31</sup>Fresard (2010) instead finds that firms with higher cash holdings do increase their market share in the short-run during tranquil times. However, he studies market shares in terms of sales and his sample only includes publicly listed firms.

cash-poor firm.<sup>32</sup>

If cash holdings enable firms to gain a competitive advantage over their rivals this effect should be stronger for firms that more likely became financially constrained. As before, since information asymmetries between borrowers and lenders tend to be more pronounced for young and small firms, we use firms' age and size as a proxy for the financial constraints that they face in the wake of a financial crisis. We examine whether the effect of cash on market share growth over the longest horizon from 2007 to 2014 differs for the subsamples of young and old firms, and for the subsamples of small and large firms. We find (Table 5) that young and small firms that are cash-rich gain market share relative to their young or small cash-poor rivals. Quantitatively, a young and cash-rich firm grew its market share by 6.7 percentage points more than a young and cash-poor firm by 2014. For small firms this number equals 12.2 percentage points. We do not find a significant effect of cash on market share growth for old or large firms.

When we again differentiate across industry characteristics, we find results that are very similar to those we found when examining fixed asset growth (Table 6). The impact of cash on market share growth is only significant in industries where firms more likely face a tightening of credit conditions during the crisis, i.e. when firms tend to be small or young. When we split industries across our measures of capital intensity, concentration and depth of crisis we do not find that the cash effect is statistically different in the two types of industries.

These findings support the hypothesis that the value of cash holdings increases during a financial crisis because financial conditions tighten. Having cash at hand provides a strategic advantage when the credit cycle unexpectedly turns, not only during the crisis episode itself but also several years thereafter.

## 5.4 Results: Cash and firm operating performance

As a final test, we examine how the competitive effect of cash affected firm value. To this end, we examine how measures of operating performance are related to relative cash.<sup>33</sup> As measures of operating performance we use the firm's cumulative profits and ROA (as defined by profits over total assets) over the period 2007-2009 and over the period 2007-2014. In addition, we examine the growth in the number of employees over the two time periods (defined by the log difference). Except for firm's profits, these variables are only available for a (very) small subset of large firms who report more detailed balance sheet information.

---

<sup>32</sup>Again we define a cash-rich firm as a firm at the 90<sup>th</sup> percentile of the relative-to-rivals cash distribution and a cash-poor firm as a firm at the 10<sup>th</sup> percentile.

<sup>33</sup>As most of our firms are SMEs that are privately owned, we cannot study the impact on firms' market-to-book ratios as a measure of market value.

We estimate a model similar to regression model (1) and control for the firm’s size, age, leverage and whether it is part of a group or publicly listed. A firm that performs well may hold more cash compared to its rivals in order to grab growth opportunities. To reduce concerns that this is affecting our results we include pre-crisis values of the respective performance variables (one and two periods lagged) in order to capture firm characteristics that may have driven the firm’s performance in the past. We again include 4-digit industry and region fixed effects. Regressions are estimated for the two horizons separately using OLS and standard errors are clustered at the 4-digit industry level. We focus exclusively on the set of firms with complete data on relative-to-rivals cash, the control variables and the respective dependent variable for both horizons.

The results in Table 7 indicate that having cash at hand when the credit cycle turns also enhances firm operating performance. Cash-rich firms accumulated more profits during the crisis and this effect was amplified during the recovery period. This finding is confirmed when we examine ROA which also grows more for cash-rich firms during the crisis and this effect is amplified during the recovery period. The only measure that does not seem to be affected by a firm’s cash position going into the crisis is employee growth. While the cash coefficient is positive and significant at the 10 percent level during the crisis, this effect disappears during the recovery period. As we only observe employment for a subset of large and old firms this may explain why we do not find an effect. Overall, these findings are consistent with the idea that having access to a liquid balance sheet when the credit cycle turns contributes positively to a firm’s operating performance.

## 6 Conclusions

This paper identifies a strong link between a firm’s pre-crisis cash holdings and its long-term investment and competitive position after a crisis. Evidence from the global financial crisis suggest that firms with high pre-crisis cash holdings were able to replace depreciating fixed assets and could even continue to invest during the global financial crisis while their cash-poor rivals had to divest. This gave cash-rich firms a competitive advantage during the recovery period, resulting in an amplification of the investment gap. This persistent and widening investment gap between cash-rich and cash-poor firms was not present in the pre-crisis period. We show that the cash-effect was present both for firms with stable and with fluctuating cash holdings. This suggests that having high or low levels of cash when the credit cycle turns, whether due to sheer (good or bad) luck or because of carefully managed cash buffers, had a strong impact on a firm’s long-term investment patterns after the crisis.

We posit that an underlying driver behind the amplification of the investment gap is

the ability of cash-rich firms to persistently outcompete their cash-poor rivals. In line with this mechanism, we find that cash holdings before the onset of the crisis had a positive effect on market share growth during the crisis and this effect was again amplified during the recovery phase. In addition we show that cash contributed positively to a firm’s operating performance.

Our findings have three key implications. First, our analysis suggests that estimates of the impact of a crisis should take long-term effects into account. Estimates that focus only on the crisis years underestimate the true effect of the downturn. Second, our findings highlight the importance of cash in helping firms preserve productive capacity when the credit cycle turns. Cash should therefore be separately monitored by policy makers and complement any analysis of the liability side of corporate balance sheets. Finally, our paper points to the need for well-designed public lending schemes to ease the funding shortages of firms in the coronavirus crisis. The self-reinforcing dynamics that our analysis uncovers highlights the importance of the provision of funds to the most productive firms in a timely manner. A delayed response or a misallocation of credit could result in industrial sectors being dominated by firms that happened to have cash at the onset of the crisis later on. Firms may hold cash going into a crisis due to sheer luck or due to prudent cash management but not necessarily because they are the most productive firms. Not past cash balances but future growth prospects should determine future growth prospects of firms.

**Figure 1: Variations in cash holdings by industry (2006)**

*Notes:* This figure plots the correlation between the mean and standard deviation of cash holdings of UK firms at the 4-digit industry level. Cash holdings are defined as deposits over total assets and measured in 2006.

**Figure 2: Auto-correlation relative cash**

*Notes:* This figure plots the distribution of the one-lag auto-correlation coefficient of relative-to-rivals cash over the period 2000 to 2006 of firms that are active during the period 2000-2014. Relative cash is calculated by subtracting from the firm's cash holdings its industry mean and divide the difference by the industry standard deviation. Industry mean and standard deviation are determined at the 4-digit level. The vertical red line marks the mean of the distribution.

**Figure 3: Investment high vs low cash firms: pre-crisis and crisis period**

**(a) Panel A: Pre-crisis period: 2001-2007**

**(b) Panel B: Crisis period: 2007-2014**

*Notes:* These figures plot the average fixed asset growth for firms in each percentile of relative-to-rivals cash within the 90 percent interquartile range. In panel A average fixed asset growth is tracked over the period 2001-2007 and in panel B over the period 2007-2014. Fixed asset growth is defined as the log difference between 2001 and year  $2001+j$  (pre-crisis period) and between 2007 and  $2007+j$  (crisis period). Relative cash is calculated by subtracting from the firm's cash holdings its industry mean and divide the difference by the industry standard deviation and is measured in 2000 for the pre-crisis period and in 2006 for the crisis period. Industry mean and standard deviation are determined at the 4-digit level.

**Figure 4: Long-term impact of cash on investment**

*Notes:* These figures plot the impact of relative-to-rivals cash on investment over different horizons using local projections. The dependent variable is the cumulative fixed asset growth between 2007 and  $2007+j$ , where  $j$  ranges from 1 to 7. The baseline regression specification (left-hand side panel) includes all the standard control variables as specified in model (1), the regression specification used in the right-hand side panel also includes controls for turnover growth. All variables are measured in 2006, except investment and turnover growth which are measured over 2005-2006 and 2006-2007. Both specifications include region and 4-digit industry fixed effects. Standard errors allow for correlation at the 4-digit industry level. The lines correspond to the estimated parameter of *Relative cash* and the dashed lines show the 90 percent confidence intervals.

**Figure 5: Estimated investment cash-rich and cash-poor firms during crisis and recovery**

*Notes:* This figure plots the estimated cumulative fixed asset growth of cash-rich and cash-poor firms and the difference between the two based on the estimated coefficients of the baseline model. The left hand side panel shows fixed asset growth between 2007 and 2009, the right hand side panel between 2007 and 2014. Cash-rich corresponds to the 90<sup>th</sup> percentile of the within industry firm distribution of *Relative cash*. Cash-poor corresponds to the 10<sup>th</sup> percentile.

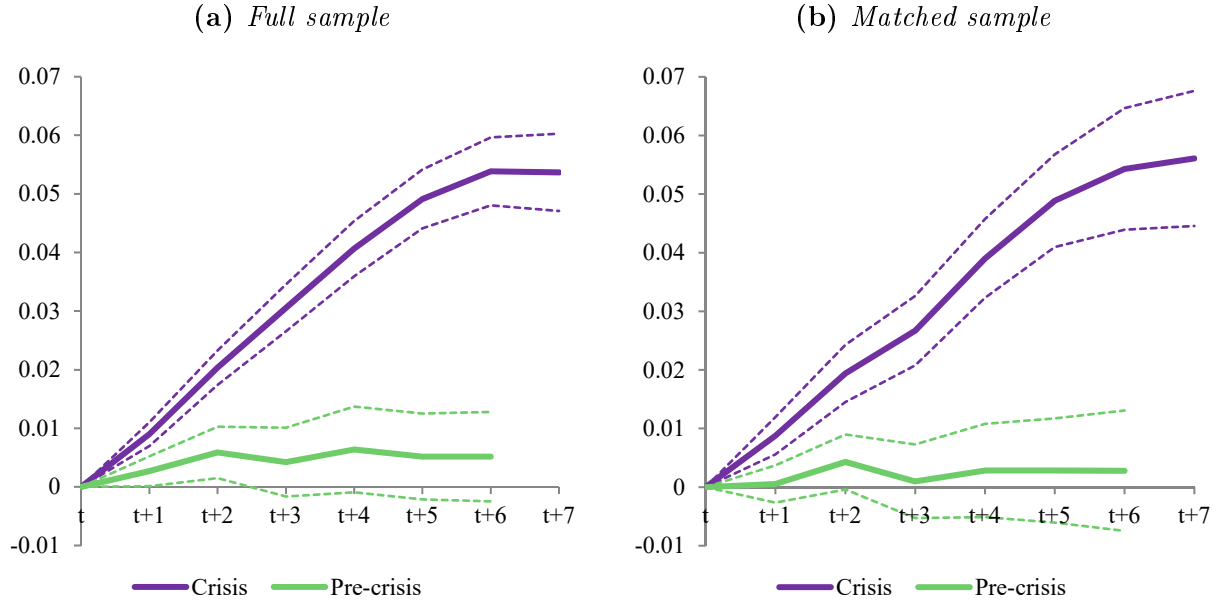

**Figure 6: Long-term impact of cash on investment - persistence of cash holdings**

*Notes:* This figure plots the impact of relative-to-rivals cash on investment over different horizons using local projections for subsets of firms with weak, intermediate or high persistence of relative-to-rivals cash holdings. Cash persistence is measured as the one-lag auto-correlation coefficient of *Relative cash* over the period 2000 to 2006. Firms with weak cash persistence are those ranked in the lower tercile of the persistence distribution, firms with intermediate persistence are those ranked above the lower and below the upper tercile of the distribution, and firms with high persistence are those ranked above the upper tercile of the distribution. The dependent variable is the cumulative fixed asset growth between 2007 and  $2007+j$ , where  $j$  ranges from 1 to 7. The regressions are based on a sub-set of 114,678 firms who report information on their cash holdings each year between 2000 and 2006. All regressions include the standard control variables and region and 4-digit industry fixed effects. Standard errors allow for correlation at the 4-digit industry level. The dark-colored lines correspond to the estimated parameter of *Relative cash* and the corresponding light-colored lines show the 90 percent confidence intervals.

**Figure 7: Long-term impact of cash on investment - crisis vs pre-crisis period**

*Notes:* These figures plot the impact of relative-to-rivals cash on investment over different horizons using local projections for the crisis and pre-crisis periods. The dependent variable is the cumulative fixed asset growth between 2007 and 2007+ $j$ , where  $j$  ranges from 1 to 7 for the crisis sample and between 2001 and 2001+ $j$ , where  $j$  ranges from 1 to 6 for the pre-crisis sample. The full sample includes all firms. The matched sample includes the subset of firms that are exactly matched on 4-digit industry, region, age category, size category and quartiles of leverage, profit, and investment with all variables measured in 2006 for the crisis sample and in 2000 for the pre-crisis sample. All regressions include the standard control variables and region and 4-digit industry fixed effects. Standard errors allow for correlation at the 4-digit industry level. The lines correspond to the estimated parameter of *Relative cash* for the two periods and the dashed lines show the 90 percent confidence intervals.

**Figure 8: Estimated long-term investment of cash-rich and cash-poor firms - crisis vs pre-crisis period**

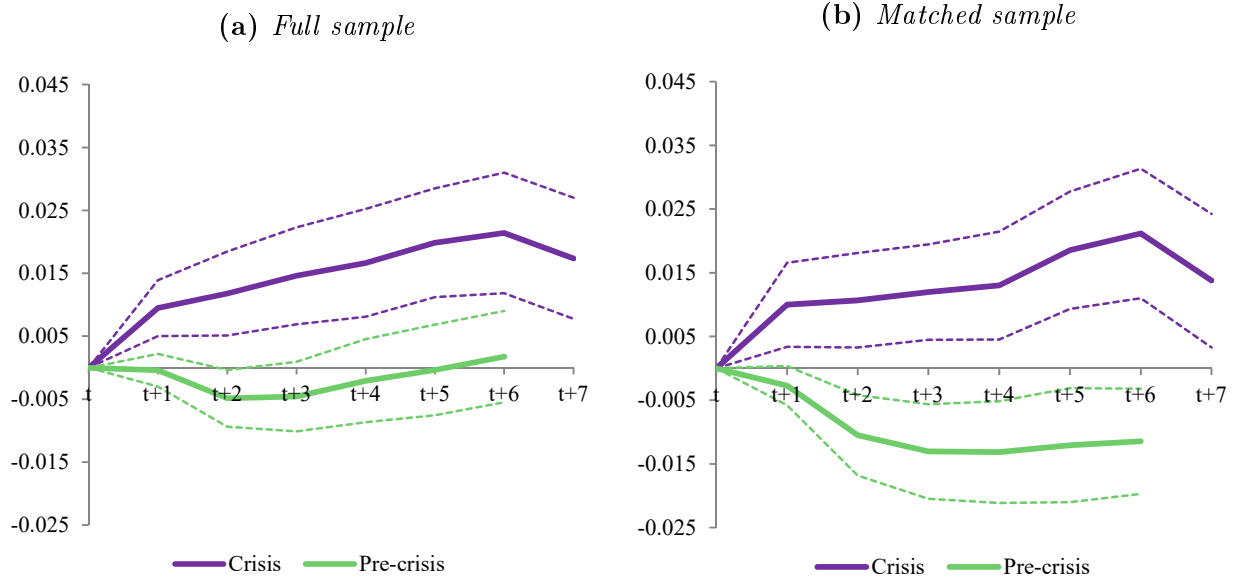

*Notes:* This figure plots the estimated cumulative fixed asset growth of cash-rich and cash-poor firms and the difference between the two based on the estimated coefficients of the baseline models for the pre-crisis and the crisis periods. The left hand side panel shows fixed asset growth between 2001 and 2007 (pre-crisis) and the right hand side panel between 2007 and 2013 (crisis). Cash-rich corresponds to the 90<sup>th</sup> percentile of the within industry firm distribution of *Relative cash*. Cash-poor corresponds to the 10<sup>th</sup> percentile.

**Figure 9: Long-term impact of cash on investment - tangible vs intangible**

*Notes:* This figure plots the impact of relative-to-rivals cash on investment in tangible and intangible fixed assets over different horizons using local projections. The dependent variable is the cumulative fixed asset growth between 2007 and 2007+ $j$ , where  $j$  ranges from 1 to 7, where fixed asset growth captures the growth in tangible, intangible or total fixed assets respectively. The regressions are based on a sub-set of 16,711 firms that report information on both tangible and intangible assets. All regressions include the standard control variables and region and 4-digit industry fixed effects. Standard errors allow for correlation at the 4-digit industry level. The dark-colored lines correspond to the estimated parameter of *Relative cash* and the corresponding light-colored lines show the 90 percent confidence intervals.

**Figure 10: Long-term impact of cash on market share - crisis vs pre-crisis period**

*Notes:* These figures plot the impact of relative-to-rivals cash on market share growth over different horizons using local projections for the crisis and pre-crisis periods. The dependent variable is the cumulative market share growth between 2007 and 2007+ $j$ , where  $j$  ranges from 1 to 7 for the crisis sample and between 2001 and 2001+ $j$ , where  $j$  ranges from 1 to 6 for the pre-crisis sample. Market share growth is defined as the percentage change of the firm's assets relative to its total industry assets (at the 4-digit industry level). The full sample includes all firms. The matched sample includes the subset of firms that are exactly matched on 4-digit industry, region, age category, size category and quartiles of leverage, profit, and investment with all variables measured in 2006 for the crisis sample and in 2000 for the pre-crisis sample. All regressions include the standard control variables and region fixed effects. Standard errors allow for correlation at the 4-digit industry level. The lines correspond to the estimated parameter of *Relative cash* for the two periods and the dashed lines show the 90 percent confidence intervals.

**Table 1: Summary statistics**

| Variable                          | Obs     | Mean  | Median | St. Dev. | Min     | Max    |
|-----------------------------------|---------|-------|--------|----------|---------|--------|
| <i>Crisis sample</i>              |         |       |        |          |         |        |
| $\Delta \ln FA$ (2007-2014)       | 235,396 | -0.06 | -0.02  | 1.00     | -3.45   | 4.09   |
| Relative cash                     | 235,396 | -0.14 | -0.42  | 0.85     | -1.42   | 2.89   |
| Leverage                          | 235,396 | 0.62  | 0.60   | 0.39     | 0.00    | 3.47   |

*Notes:* This table shows the summary statistics of the key variables used in the analysis

**Table 2: Pre-crisis characteristics high cash and low cash firms**

| Variable      | High relative cash | Low relative cash | Difference |     |
|---------------|--------------------|-------------------|------------|-----|
| Cash holdings | 0.57               | 0.03              | 0.54       | *** |
| Size (th)     | 684                | 1,700             | -1015      | *** |
| Young (<10y)  | 0.58               | 0.56              | 0.02       | *** |
| Fixed assets  | 0.20               | 0.44              | -0.24      | *** |
| Leverage      | 0.48               | 0.77              | -0.29      | *** |
| Profit        | 0.47               | 0.15              | 0.32       | *** |
| Investment    | 0.04               | 0.04              | 0.00       |     |

*Notes:* This table presents difference-in-difference estimates from a Mann-Whitney two-sided  $t$ -test on selected pre-crisis balance sheet characteristics of firms with high and low cash relative to their industry rivals. High relative cash firms are those firms in the top quartile of relative-to-rivals cash distribution and low relative cash firms are those in the bottom quartile of the distribution as measured in 2006. *Cash holdings* denotes the firm's deposits over total assets. *Size* denotes the firms' total assets (in thousands). *Young* is a dummy which is one if the firm is 10 years or younger. *Fixed assets* denotes the firms' share of fixed assets over total assets. *Leverage* denotes the share of total liabilities over total assets. *Profit* denotes the firm's profit over total assets. *Investment* denotes the average of the log difference of the firm's fixed assets between 2005 and 2006 and between 2006 and 2007. All variables are measured in 2006 unless otherwise specified. \*\*\* indicates significance at the 1% level, \*\* at the 5% level, and \* at the 10% level.

**Table 3: Cross-firm impact cash on investment - 2007-2014**

| Financial constraints criteria | Constrained    | Unconstrained | Difference (p-value) |
|--------------------------------|----------------|---------------|----------------------|
| <i>Age</i>                     | <i>Young</i>   | <i>Old</i>    |                      |
|                                | 0.068***       | 0.034***      | 0.00***              |
|                                | (0.005)        | (0.007)       |                      |
|                                | <i>132,142</i> | <i>58,162</i> |                      |
| <i>Size</i>                    | <i>Small</i>   | <i>Large</i>  |                      |
|                                | 0.087***       | 0.060***      | 0.14                 |
|                                | (0.009)        | (0.009)       |                      |
|                                | <i>58,336</i>  | <i>58,920</i> |                      |

*Notes:* This table presents the estimates of relative-to-rivals cash on investment across different groups or firms. Firms are classified on the basis of proxies for financial constraints based on their age and size. Constrained firms in terms of age are firms that are 10 years or younger and unconstrained firms are firms older than 20 years. Constrained firms in terms of size are firms in the bottom quartile of the total asset distribution and unconstrained firms are those in the top quartile. Age and size are measured in 2006. The dependent variable is cumulative fixed asset growth between 2007 and 2014. All regressions include the control variables as specified in model (1) and include 4-digit industry and region fixed effects. Standard errors allow for correlation at the 4-digit industry level. The last column presents the p-value associated with the F-tests that compare the coefficients between the constrained and unconstrained subgroups. The number of firms in each group is in italics. Standard errors are in parentheses. \*\*\* indicates significance at the 1% level, \*\* at the 5% level, and \* at the 10% level.

**Table 4: Cross-industry impact cash on investment - 2007-2014**

| Industry criteria | Low                                   | High                                 | Difference (p-value) |
|-------------------|---------------------------------------|--------------------------------------|----------------------|
| <i>Panel A</i>    |                                       |                                      |                      |
| Age               | 0.068***<br>(0.006)<br><i>86,540</i>  | 0.047***<br>(0.005)<br><i>38,790</i> | 0.00***              |
| Size              | 0.070***<br>(0.005)<br><i>111,749</i> | 0.038***<br>(0.008)<br><i>48,557</i> | 0.00***              |
| <i>Panel B</i>    |                                       |                                      |                      |
| Capital intensity | 0.057***<br>(0.008)<br><i>51,963</i>  | 0.061***<br>(0.007)<br><i>60,804</i> | 0.71                 |
| Concentration     | 0.046***<br>(0.006)<br><i>114,057</i> | 0.056***<br>(0.013)<br><i>29,359</i> | 0.50                 |
| Depth crisis      | 0.058***<br>(0.006)<br><i>82,639</i>  | 0.046***<br>(0.008)<br><i>33,547</i> | 0.25                 |

*Notes:* This table presents the estimates of relative-to-rivals cash on investment across different industries. The dependent variable is the log difference of fixed assets between 2007 and 2014. Industries are classified on the basis of different age criteria. *Age* captures the industry mean firm age and *Size* the industry mean firm size. *Capital intensity* captures the industry mean firm ratio of fixed assets over total assets. *Concentration* equals the industry's Herfindahl index based on turnover. *Depth crisis* captures the mean firm growth in value added between 2007 and 2010. All measures are calculated at the 4-digit industry level. *Low* industries are those ranked in the bottom quartile of the respective distribution and *High* industries are those ranked in the top quartile of the same distribution, except for *Depth crisis* where *Low* captures the top quartile and *High* the bottom quartile. All industry characteristics, except *Depth crisis*, are measured in 2006. The dependent variable is cumulative fixed asset growth between 2007 and 2014. All regressions include the control variables as specified in model (1) and include 4-digit industry and region fixed effects. Standard errors allow for correlation at the 4-digit industry level. The last column presents the p-value associated with the F-tests that compare the coefficients between the high and low subgroups. The number of firms in each group is in italics. Standard errors are in parentheses. \*\*\* indicates significance at the 1% level, \*\* at the 5% level, and \* at the 10% level.

**Table 5: Cross-firm impact cash on market share - 2007-2014**

| Financial constraints criteria | Constrained                           | Unconstrained                      | Difference (p-value) |
|--------------------------------|---------------------------------------|------------------------------------|----------------------|
| <i>Age</i>                     | <i>Young</i>                          | <i>Old</i>                         |                      |
|                                | 0.031***<br>(0.008)<br><i>125,164</i> | -0.007<br>(0.007)<br><i>56,933</i> | 0.00***              |
| <i>Size</i>                    | <i>Small</i>                          | <i>Large</i>                       |                      |
|                                | 0.057***<br>(0.007)<br><i>53,733</i>  | 0.001<br>(0.008)<br><i>57,789</i>  | 0.00***              |

*Notes:* This table presents the estimates of relative-to-rivals cash on market share growth across different groups or firms. Firms are classified on the basis of proxies for financial constraints based on their age and size. Constrained firms in terms of age are firms that are 10 years or younger and unconstrained firms are firms older than 20 years. Constrained firms in terms of size are firms in the bottom quartile of the total asset distribution and unconstrained firms are those in the top quartile. Age and size are measured in 2006. The dependent variable is cumulative market share growth between 2007 and 2014. Market share growth is defined as the percentage change of the firm's assets relative to its total industry assets (at the 4-digit industry level). All regressions include the control variables as specified in model (2) and include region fixed effects. Standard errors allow for correlation at the 4-digit industry level. The last column presents the p-value associated with the F-tests that compare the coefficients between the constrained and unconstrained subgroups. The number of firms in each group is in italics. Standard errors are in parentheses. \*\*\* indicates significance at the 1% level, \*\* at the 5% level, and \* at the 10% level.

**Table 6: Cross-industry impact cash on market share growth - 2007-2014**

| Industry criteria | Low                                   | High                                 | Difference (p-value) |
|-------------------|---------------------------------------|--------------------------------------|----------------------|

*Notes:* This table presents the estimates of relative-to-rivals cash on market share growth across different industries. Market share growth is defined as the percentage change of the firm's assets relative to its total industry assets (at 4-digit industry level). Industries are classified on the basis of different age criteria. *Age* captures the industry mean firm age and *Size* the industry mean firm size. *Capital intensity* captures the industry mean firm ratio of fixed assets over total assets. *Concentration* equals the industry's Herfindahl index based on turnover. *Depth crisis* captures the mean firm growth in value added between 2007 and 2010. All measures are calculated at the 4-digit industry level. *Low* industries are those ranked in the bottom quartile of the respective distribution and *High* industries are those ranked in the top quartile of the same distribution, except for *Depth crisis* where *Low* captures the top quartile and *High* the bottom quartile. All industry characteristics, except *Depth crisis*, are measured in 2006. The dependent variable is cumulative market share growth between 2007 and 2014. Market share growth is defined as the percentage change of the firm's assets relative to its total industry assets (at the 4-digit industry level). All regressions include the control variables as specified in model (2) and include region fixed effects. Standard errors allow for correlation at the 4-digit industry level. The last column presents the p-value associated with the F-tests that compare the coefficients between the high and low subgroups. The number of firms in each group is in italics. Standard errors are in parentheses. \*\*\* indicates significance at the 1% level, \*\* at the 5% level, and \* at the 10% level.

**Table 7: Cash and firm performance**

| Dependent variable     | $\Sigma$ Profit     |                      | $\Sigma$ ROA        |                     | $\Delta \ln$ Employees |                  |
|------------------------|---------------------|----------------------|---------------------|---------------------|------------------------|------------------|

| Nr. observations       | <i>220,665</i>      | <i>220,665</i>       | <i>220,665</i>      | <i>220,665</i>      | <i>8,958</i>           | <i>8,958</i>     |

*Notes:* This table presents the estimates of relative-to-rivals cash on different performance measures. The dependent variable is cumulative profit (columns 1 and 2), cumulative ROA (columns 3 and 4), and the cumulative growth in the number of employees (columns 5 and 6). Cumulative changes and growth rates are measured between 2007 and 2009 in the uneven columns and between 2007 and 2014 in the even columns. All regressions include all control variables as specified in model (1) plus the first and second lag of the respective dependent variables. All regressions include region and 4-digit industry fixed effects. Standard errors allow for correlation at the 4-digit industry level. Standard errors are in parentheses. \*\*\* indicates significance at the 1% level, \*\* at the 5% level, and \* at the 10% level.

**Appendix Figure 1 - Correlation annual change in relative cash and one period ahead fixed asset growth**

*Notes:* This figure plots the distribution of the correlation coefficient of the annual change in relative cash and the one period ahead annual change in fixed asset growth for firms with weak cash persistence (i.e. those ranked in the lower tercile of the persistence distribution). Annual cash changes are measured for the years 2000 to 2006 and annual fixed asset growth for the years 2001 to 2007. The vertical red line marks the mean of the distribution.

**Appendix Figure 2 - Long-term impact of cash on investment - different tranquil periods**

*Notes:* This figure compares the impact of relative-to-rivals cash on investment for different pre-crisis periods with the impact for the crisis period. The dependent variable is the cumulative fixed asset growth between year  $t$  and year  $t+j$ , where  $j$  ranges from 1 to 6 and where  $t$  equals 2001, 2002, 2003 or 2007. *Relative cash* is measured in year  $t-1$  for all regressions. All regressions include the standard control variables as specified in model (1) and region and 4-digit industry fixed effects. Standard errors allow for correlation at the 4-digit industry level. The lines correspond to the estimated parameter of *Relative cash* for the four periods.

**Appendix Table A1 - Variable Definitions and Sources**

|   | <b>Variable</b>            | <b>Definition</b>                                                                                                                                                                                                                                             | <b>Source</b> |
|---|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|
| Σ | ΔlnFA                      | Log difference of fixed assets between 2007 and year 2007+ $j$ (crisis period) or between 2001 and 2001 + $j$ (pre-crisis period)                                                                                                                             | FAME          |
|   | Relative cash              | Cash holdings of the firm minus the (4-digit) industry mean cash holdings and divided by the (4-digit) industry standard deviation. Cash holdings equal deposits divided by total assets.                                                                     | FAME          |
|   | Leverage                   | Total liabilities over total assets                                                                                                                                                                                                                           | FAME          |
|   | Size                       | Log of total assets                                                                                                                                                                                                                                           | FAME          |
|   | Mature                     | Dummy equal to one if the firm is between 10 and 20 years old                                                                                                                                                                                                 | FAME          |
|   | Old                        | Dummy equal to one if the firm is older than 20 years                                                                                                                                                                                                         | FAME          |
|   | Group                      | Dummy equal to one if the firm has a parent or is part of a group, defined as a firm that reports an ultimate owner in FAME                                                                                                                                   | FAME          |
|   | Public                     | Dummy equal to one if the firm is publicly listed                                                                                                                                                                                                             | FAME          |
|   | Profit                     | Profit over total assets                                                                                                                                                                                                                                      | FAME          |
|   | Pre-Investment             | Log difference of fixed assets between 2005 and 2006 and between 2006 and 2007 (crisis period) or between 1999 and 2000 and between 2000 and 2001 (pre-crisis period)                                                                                         | FAME          |
|   | Pre-Turnover growth        | Log difference of turnover between 2005 and 2006 and between 2006 and 2007 (crisis period) or between 1999 and 2000 and between 2000 and 2001 (pre-crisis period)                                                                                             | FAME          |
|   | %ΔMShare                   | Growth rate of the firm's market share between 2007 and year 2007+ $j$ (crisis period) or between 2001 and 2001 + $j$ (pre-crisis period), where market share is defined as the ratio of the firm's assets over the total industry assets (at 4-digit level). | FAME          |
|   | Industry age               | Average age of firms in a 4-digit industry                                                                                                                                                                                                                    | FAME          |
|   | Industry size              | Average size of firms in a 4-digit industry                                                                                                                                                                                                                   | FAME          |
|   | Industry capital intensity | Average fixed assets over total assets of firms in a 4-digit industry                                                                                                                                                                                         | FAME          |
|   | Industry HHI               | Herfindahl-Hirschman Index (HHI) based on turnover for each 4-digit industry                                                                                                                                                                                  | ONS           |
|   | Industry depth crisis      | Average growth of value added by firms in a 4-digit industry between 2007 and 2010                                                                                                                                                                            | ONS           |
|   | Σ Profit                   | Cumulative profits of the firm over the period 2007 to 2009/2014                                                                                                                                                                                              | FAME          |
|   | Σ ROA                      | Cumulative ROA (profit/ta) of the firm over the period 2007 to 2009/2014                                                                                                                                                                                      | FAME          |
|   | Δln Employees              | Log difference of number of employees between 2007 and 2009/2014                                                                                                                                                                                              | FAME          |

*Notes:* This table shows variables definitions and data sources for all the variables used in the empirical analysis.
